How to Draw a Basic Pyrometer Optical Diagram

For creating an optical diagram based on the written 90% optical specification

Approximate "cone of vision" when the Spot Size Calculator does not include a specific model or special build model

Start with a centre line

Add the lens diameter (quoted spot size at 0mm distance)

MM = 30mm @ 0mm distance TX= 18mm @ 0mm distance T4.0 (LT, G5 etc) = 22.5 @ 0mm distance Mi3 = 6mm @ 0mm distance Endurance = 15mm @ 0mm distance

Add the spot size diameter (quoted spot size at focus distance) at a distance (relative scale)

Draw the 1st line (ray)

Draw the 2nd line (ray)

Draw the 3rd line (ray)

Draw the 4th line (ray)

Measure (using scale) to determine spot size at any distance

Lens diameter

Spot size at focus point diameter

Far-field spot size diameter

Measure (using scale) to determine spot size at any distance

Remember that this is the 90% spot size

Lens diameter

Spot size at focus point diameter

90% spot size = 10% of the energy for the measurement comes from outside the stated spot size	spot size
The diameter of this "practical" 100% spot size (90% spot size x n>1) is a function of optical quality (Endurance is better than Mi3)	
	diamota

Far-field е diameter

Measure (using scale) to determine spot size at any distance

Remember that this is the 90% spot size

100% spot size will always be larger

Lens diameter

Spot size at focus point diameter

90% spot size = 10% of the energy for the measurement comes from outside the stated spot size The diameter of this "practical" 100% spot size (90% spot size x n>1) is a function of optical quality (Endurance is better than Mi3) This "10% energy area" also has more influence on the reading for an LT sensor than a 1M sensor – function of wavelength Far-fi spot : diamc.c.
